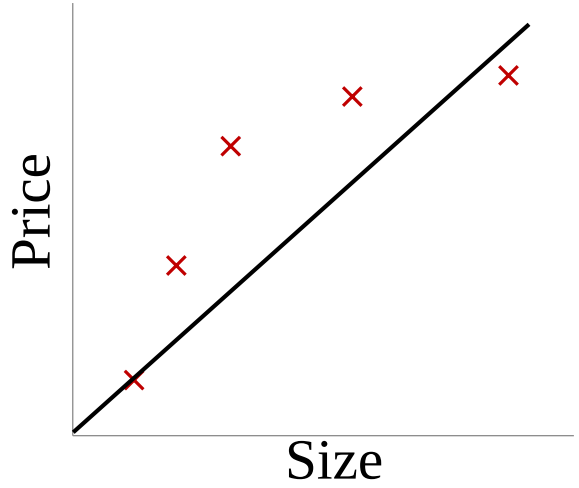
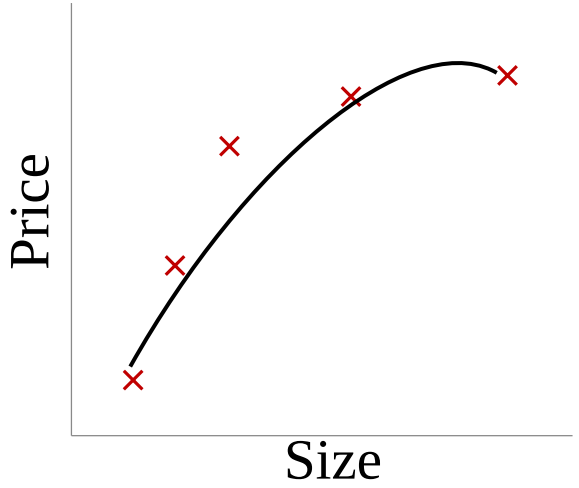
Example: Linear regression (housing prices)



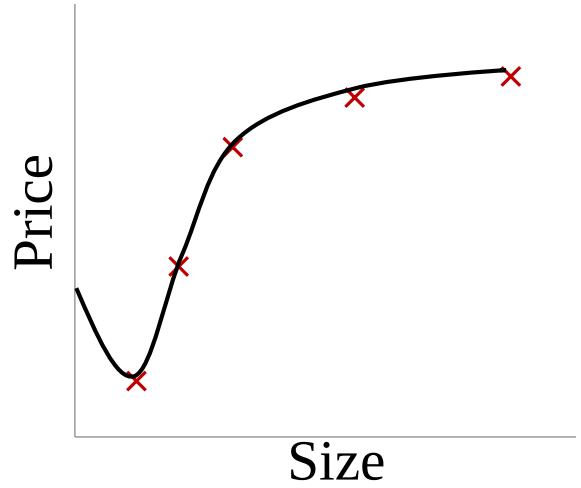
$\theta_0 + \theta_1 x$

Underfitting: “High Bias”



$\theta_0 + \theta_1 x + \theta_2 x^2$

Correct Fit

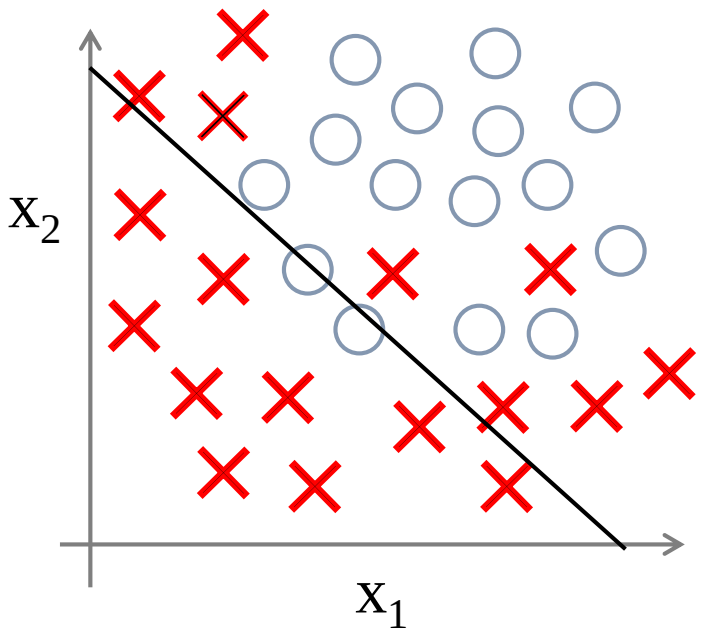


$\theta_0 + \theta_1 x + \theta_2 x^2 + \theta_3 x^3 + \theta_4 x^4$

Overfitting: “High Variance”

Overfitting: If we have too many features, the learned hypothesis may fit the training set very well ($J(\theta) = \frac{1}{2m} \sum_{i=1}^{m} (h_\theta(x^{(i)}) - y^{(i)})^2 \approx 0$), but fail to generalize to new examples (predict prices on new examples).

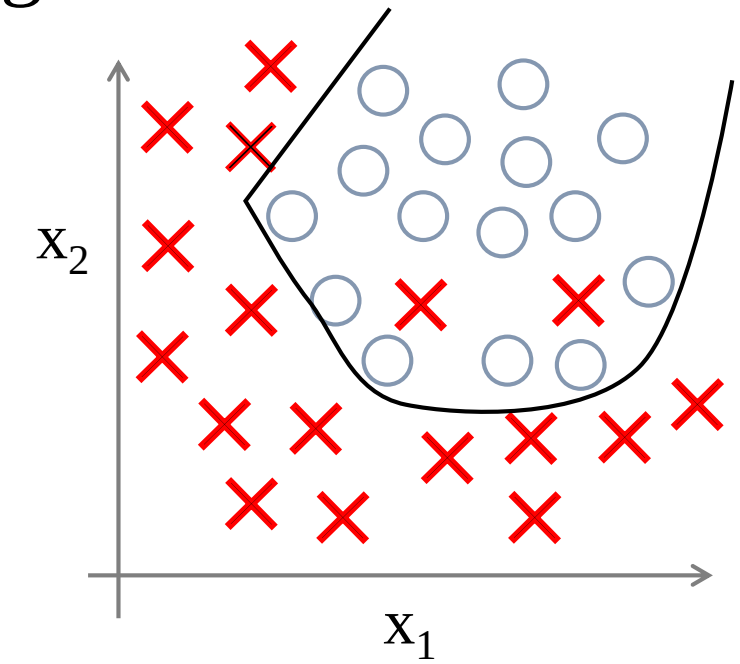
Example: Logistic regression



$h_\theta(x) = g(\theta_0 + \theta_1 x_1 + \theta_2 x_2)$

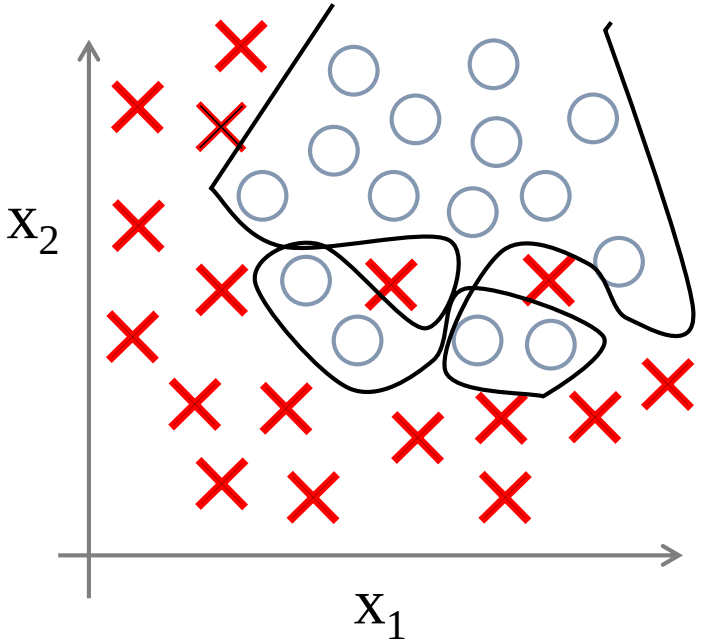
(g = sigmoid function)

Underfitting: “High Bias”



$g(\theta_0 + \theta_1 x_1 + \theta_2 x_2 + \theta_3 x_1^2 + \theta_4 x_2^2 + \theta_5 x_1 x_2)$

Correct Fit



$g(\theta_0 + \theta_1 x_1 + \theta_2 x_1^2 + \theta_3 x_1^2 x_2 + \theta_4 x_1^2 x_2^2 + \theta_5 x_1^2 x_2^3 + \theta_6 x_1^3 x_2 + \dots)$

Overfitting: “High Variance”

Addressing overfitting:

Options:

1. Reduce number of features.
   - Manually select which features to keep.
   - Model selection algorithm (later in course).
2. Regularization.
   - Keep all the features, but reduce magnitude/values of parameters θ_j
   - Works well when we have a lot of features, each of which contributes a bit to predicting y.

Regularization

Regularized Linear Regression

J(theta) = 1/2m [summation i= 1 to m (h(x)^i - yi)^2 + lamda summation j=1 to n theta j^2]

Regularized Linear Regression

$$J(\theta) = \frac{1}{2m}\left[\sum_{i=1}^{m}(h(x)^i - y_i)^2 + \lambda \sum_{j=1}^{n}\theta_j^2\right]$$

Regularized Logistic Regression

$$J(\theta) = -\left[\frac{1}{m}\sum_{i=1}^{m} y_i \log(h(x)^i) + (1-Y_i)\log(1-h(x)^i)\right] + \frac{\lambda}{2m}\sum_{j=1}^{n}(\theta_j)^2$$

Gradient Descent Algorithm

{

Theta 0:= theta 0 - alpha (1/m) summation i = 1 to m (h(x)^i - y i) X0^i
Theta j := theta j - alpha[1/m summation i = 1 to m (h(x)i - yi)Xj^i - lamda/m thetaj

(for j = 1, 2, 3, ...n)

}

Gradient Descent Algorithm

{

Theta 0:= theta 0 - alpha (1/m) summation i = 1 to m (h(x)^i - y i) X0^i
Theta j := theta j - alpha[1/m summation i = 1 to m (h(x)i - yi)Xj^i - lamda/m thetaj

(for j = 1, 2, 3, ...n)

}

penalize the features that has higher value of slope
lamda = 0 to +ve values

Gradient Descent Algorithm

{

Theta 0:= theta 0 - alpha (1/m) summation i = 1 to m (h(x)^i - y i) X0^i
Theta j := theta j - alpha[1/m summation i = 1 to m (h(x)i - yi)Xj^i - lamda/m thetaj

(for j = 1, 2, 3, ...n)

}

penalize the features that has higher value of slope
lamda = 0 to +ve values

Ridge regression & lasso regression

ridge regression

lamda(slope)^2

Lasso regression

lamda(absolute value of the slope)

ridge regression

lamda(slope)^2

Lasso regression

lamda(absolute value of the slope)

ridge regression

lamda(slope)^2 closely equal to zero

Lasso regression

lamda(absolute value of the slope) = zero

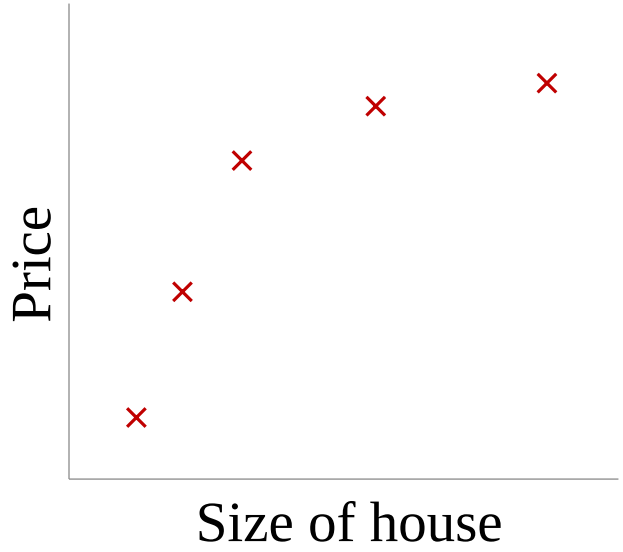
ridge regression — when most predictors impact the response

lamda(slope)^2 — closely equal to zero

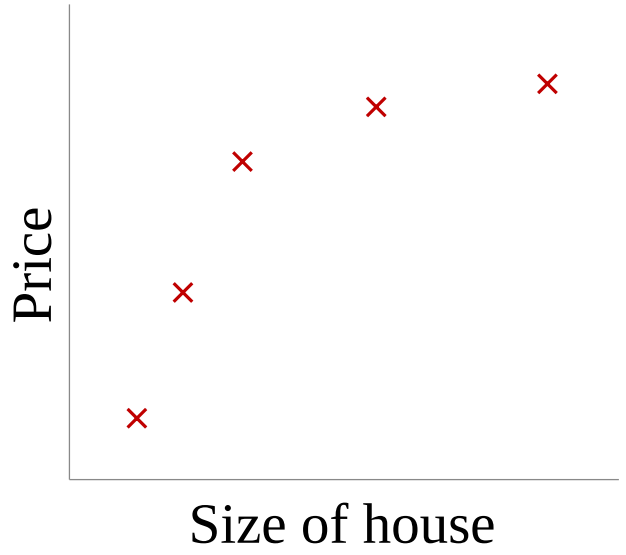
Lasso regression — when only a few predictors actually influence the response

lamda(absolute value of the slope) = zero

Intuition



$$\theta_0 + \theta_1 x + \theta_2 x^2$$



$$\theta_0 + \theta_1 x + \theta_2 x^2 + \theta_3 x^3 + \theta_4 x^4$$

Suppose we penalize and make θ_3, θ_4 really small.

$$\min_\theta \frac{1}{2m} \sum_{i=1}^{m} (h_\theta(x^{(i)}) - y^{(i)})^2$$

Regularization.

Small values for parameters $\theta_0, \theta_1, \ldots, \theta_n$

- "Simpler" hypothesis
- Less prone to overfitting

Housing:

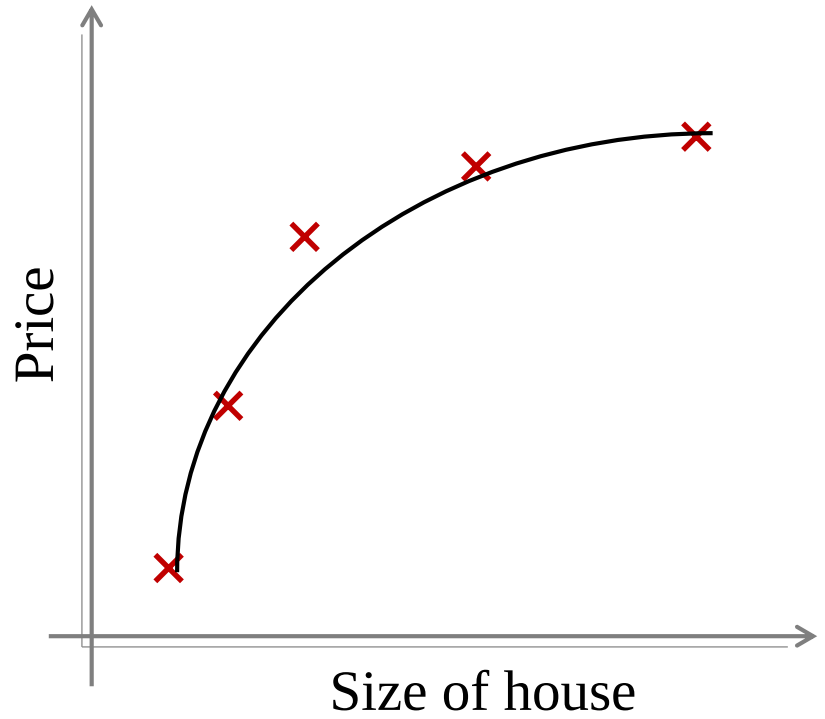
- Features: $x_1, x_2, \ldots, x_{100}$
- Parameters: $\theta_0, \theta_1, \theta_2, \ldots, \theta_{100}$

$$J(\theta) = \frac{1}{2m} \sum_{i=1}^{m} (h_\theta(x^{(i)}) - y^{(i)})^2$$

Regularization.

$$J(\theta) = \frac{1}{2m}\left[\sum_{i=1}^{m}(h_\theta(x^{(i)}) - y^{(i)})^2 + \lambda \sum_{j=1}^{n}\theta_j^2\right]$$

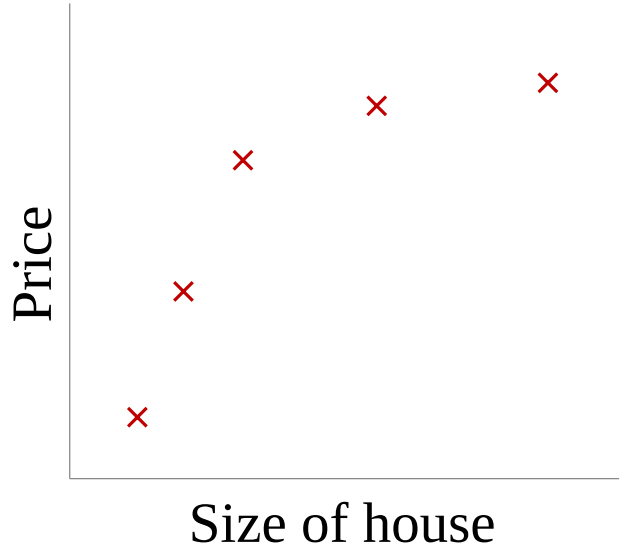
$$\min_\theta J(\theta)$$



In regularized linear regression, we choose θ to minimize

$$J(\theta) = \frac{1}{2m}\left[\sum_{i=1}^{m}(h_\theta(x^{(i)}) - y^{(i)})^2 + \lambda\sum_{j=1}^{n}\theta_j^2\right]$$

What if λ is set to an extremely large value (perhaps for too large for our problem, say $\lambda = 10^{10}$)?



$$\theta_0 + \theta_1 x + \theta_2 x^2 + \theta_3 x^3 + \theta_4 x^4$$

Regularized linear regression

$$J(\theta) = \frac{1}{2m}\left[\sum_{i=1}^{m}(h_\theta(x^{(i)}) - y^{(i)})^2 + \lambda \sum_{j=1}^{n}\theta_j^2\right]$$

$$\min_\theta J(\theta)$$

Gradient descent

Repeat $\{$

$$\theta_0 := \theta_0 - \alpha \frac{1}{m} \sum_{i=1}^{m} (h_\theta(x^{(i)}) - y^{(i)}) x_0^{(i)}$$

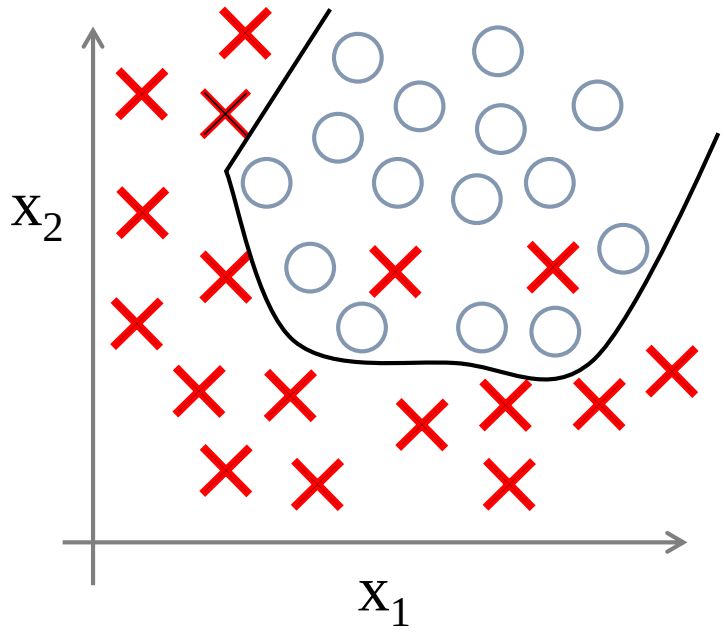
$$\theta_j := \theta_j - \alpha \frac{1}{m} \sum_{i=1}^{m} (h_\theta(x^{(i)}) - y^{(i)}) x_j^{(i)}$$

$$(j = 0, 1, 2, 3, \ldots, n)$$

$\}$

$$\theta_j := \theta_j (1 - \alpha \frac{\lambda}{m}) - \alpha \frac{1}{m} \sum_{i=1}^{m} (h_\theta(x^{(i)}) - y^{(i)}) x_j^{(i)}$$

Regularized logistic regression.



$$h_\theta(x) = g(\theta_0 + \theta_1 x_1 + \theta_2 x_1^2 + \theta_3 x_1^2 x_2 + \theta_4 x_1^2 x_2^2 + \theta_5 x_1^2 x_2^3 + \dots)$$

Cost function:

$$J(\theta) = -\left[\frac{1}{m}\sum_{i=1}^{m} y^{(i)} \log h_\theta(x^{(i)}) + (1 - y^{(i)}) \log(1 - h_\theta(x^{(i)}))\right]$$

$$+ \frac{lambda}{2m} summation\ i = 1\ to\ n\ thetaj2$$

Gradient descent

Repeat $\{$

$$\theta_0 := \theta_0 - \alpha \frac{1}{m} \sum_{i=1}^{m} (h_\theta(x^{(i)}) - y^{(i)}) x_0^{(i)}$$

$$\theta_j := \theta_j - \alpha \quad \frac{1}{m} \sum_{i=1}^{m} (h_\theta(x^{(i)}) - y^{(i)}) x_j^{(i)}$$

$$(j = \cancel{0}, 1, 2, 3, \ldots, n)$$

$\}$

RIDGE & LASSO REGRESSION

- Both the techniques are adopted to **overcome the overfitting issue**.
- Lasso regression stands for Least Absolute Shrinkage and Selection Operator & it tends to make coefficients to absolute zero as compared to Ridge which never sets the value of coefficient to absolute zero.
- **Limitation of Ridge Regression:** Ridge regression decreases the complexity of a model but does not reduce the number of variables since it never leads to a coefficient been zero rather only minimizes it. Hence, this model is not good for feature reduction.
- **Limitation of Lasso Regression:** Lasso sometimes struggles with some types of data. Lasso will pick at most n predictors as non-zero, even if all predictors are relevant (or may be used in the test set).
- If **there are two or more highly collinear variables then LASSO regression select one of them randomly** which is not good for the interpretation of data.
