Classification: Basic Concepts and Decision Trees

Classification: Definition

- Given a collection of records (training set)
 - Each record contains a set of attributes, one of the attributes is the class.
- Find a model for class attribute as a function of the values of other attributes.
- Goal: <u>previously unseen</u> records should be assigned a class as accurately as possible.
 - A test set is used to determine the accuracy of the model. Usually, the given data set is divided into training and test sets, with training set used to build the model and test set used to validate it.

Confusion Matric

A confusion matrix (Kohavi and Provost, 1998) contains information about actual and predicted classifications done by a classification system. Performance of such systems is commonly evaluated using the data in the matrix.

- a is the number of correct predictions that an instance is negative,
- b is the number of incorrect predictions that an instance is positive,
- c is the number of incorrect of predictions that an instance negative, and
- d is the number of correct predictions that an instance is positive.

Confusion Matrix

		Pred	icted
		Negative	Positive
A ctual	Negative	а	b
Actual	Positive	С	d

Confusion matrix

- Several standard terms have been defined for the 2 class matrix:
- The accuracy (AC) is the proportion of the total number of predictions that were correct. It is determined using the equation: AC = a + d / a + b + c + d
- The recall or true positive rate (TP) is the proportion of positive cases that were correctly identified, as calculated using the equation:

$$TP = \frac{d}{c+d}$$

- The false positive rate (FP) is the proportion of negatives cases that were incorrectly classified as positive, as calculated using the equation:
 FP = b / a + b
- The *true negative rate* (TN) is defined as the proportion of negatives cases that were classified correctly, as calculated using the equation: $TN = \frac{a}{a+b}$

- The *false negative rate* (*FN*) is the proportion of positives cases that were incorrectly classified as negative, as calculated using the equation: $FN = \frac{c}{c+d}$
- Finally, *precision* (P) is the proportion of the predicted positive cases that were correct, as calculated using the equation: $P = \frac{d}{b+d}$

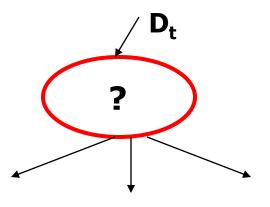

Decision Tree Induction

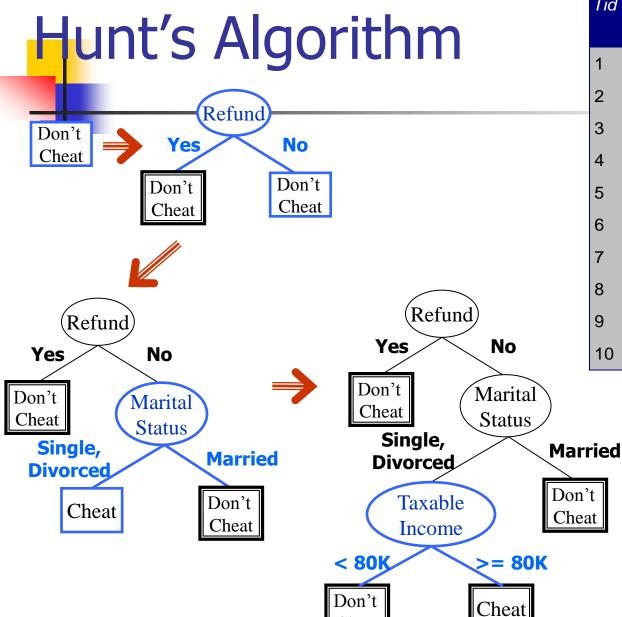

- Many Algorithms:
 - Hunt's Algorithm (one of the earliest)
 - SLIQ

General Structure of Hunt's Algorithm

- Let D_t be the set of training records that reach a node t
- General Procedure:
 - If D_t contains records that belong the same class y_t, then t is a leaf node labeled as y_t
 - If D_t is an empty set, then t is a leaf node labeled by the default class, y_d
 - If D_t contains records that belong to more than one class, use an attribute test to split the data into smaller subsets. Recursively apply the procedure to each subset.

Tree Induction

- Greedy strategy.
 - Split the records based on an attribute test that optimizes certain criterion.

Issues

- Determine how to split the records
 - How to specify the attribute test condition?
 - How to determine the best split?
- Determine when to stop splitting

Tree Induction

- Greedy strategy.
 - Split the records based on an attribute test that optimizes certain criterion.

Issues

- Determine how to split the records
 - How to specify the attribute test condition?
 - How to determine the best split?
- Determine when to stop splitting

How to Specify Test Condition?

- Depends on attribute types
 - Nominal
 - Ordinal
 - Continuous

- Depends on number of ways to split
 - 2-way split
 - Multi-way split

Splitting Based on Nominal Attributes

Multi-way split: Use as many partitions as distinct values.

Binary split: Divides values into two subsets.
 Need to find optimal partitioning.

Splitting Based on Ordinal Attributes

Multi-way split: Use as many partitions as distinct values.

Binary split: Divides values into two subsets.

Medium

Small

| Size | Need to find optimal partitioning. | OR | Size | Small | Small

Large

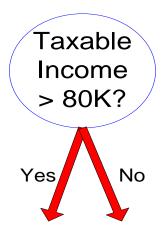

Splitting Based on Continuous Attributes

- Different ways of handling
 - Discretization to form an ordinal categorical attribute
 - Static discretize once at the beginning
 - Dynamic ranges can be found by equal interval bucketing, equal frequency bucketing

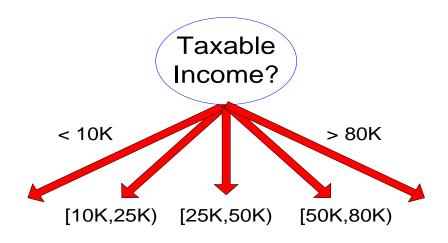

(percentiles), or clustering.

- Binary Decision: (A < v) or (A ≥ v)</p>
 - consider all possible splits and finds the best

Splitting Based on Continuous Attributes

(i) Binary split

(ii) Multi-way split

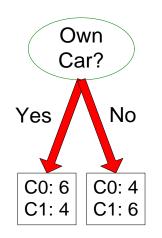

Tree Induction

- Greedy strategy.
 - Split the records based on an attribute test that optimizes certain criterion.

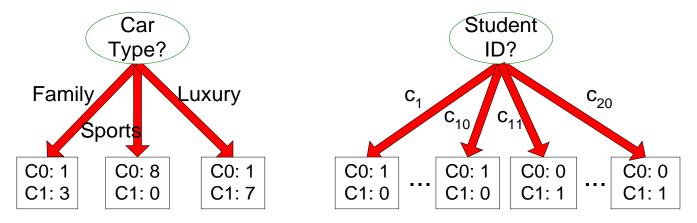

Issues

- Determine how to split the records
 - How to specify the attribute test condition?
 - How to determine the best split?
- Determine when to stop splitting

How to determine the Best Split

Before Splitting: 10 records of class 0, 10 records of class 1

Which test condition is the best?

How to determine the Best Split

- Greedy approach:
 - Nodes with homogeneous class distribution are preferred
- Need a measure of node impurity:

C0: 5 C1: 5

Nonhomogeneous,

High degree of impurity

C0: 9 C1: 1

Homogeneous,

Low degree of impurity

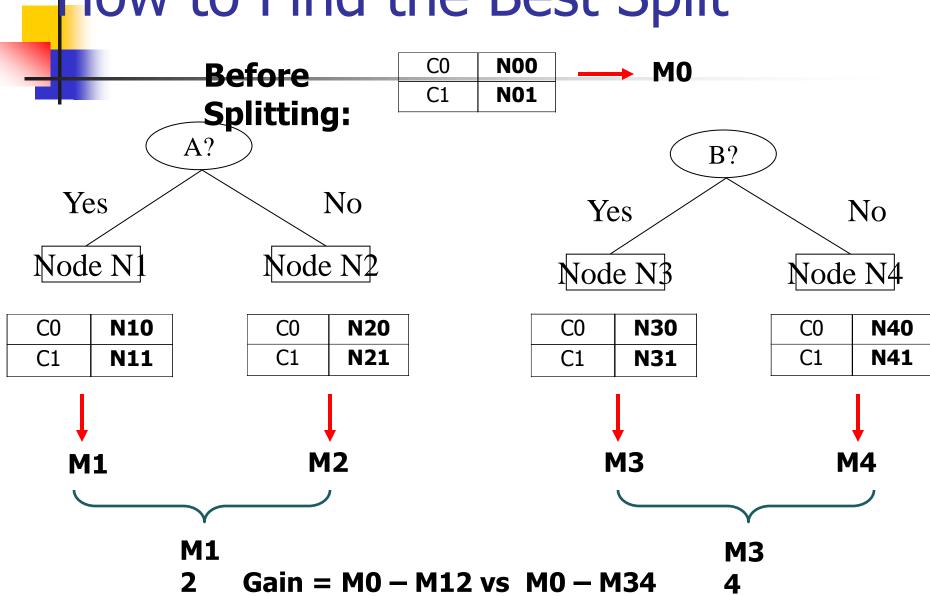

Measures of Node Impurity

Gini Index

Entropy

Misclassification error

How to Find the Best Split

Measure of Impurity: GINI

Gini Index for a given node t:

$$GINI(t) = 1 - \sum_{j} [p(j|t)]^{2}$$

(NOTE: $p(j \mid t)$ is the relative frequency of class j at node t).

- Maximum (1 1/n_c) when records are equally distributed among all classes, implying least interesting information
- Minimum (0.0) when all records belong to one class, implying most interesting information

Gini=0.000	
C2	6
C1	0

C1	1
C2	5
Gini=0.278	

C1	2	
C2	4	
Gini=0.444		

C1	3	
C2	3	
Gini=0.500		

Examples for computing GINI $GINI(t) = 1 - \sum [p(j|t)]^{2}$

$$GINI(t) = 1 - \sum_{j} [p(j|t)]^{2}$$

$$P(C1) = 0/6 = 0$$
 $P(C2) = 6/6 = 1$
 $Gini = 1 - P(C1)^2 - P(C2)^2 = 1 - 0 - 1$
 $= 0$

C1	1
C2	5

$$P(C1) = 1/6$$
 $P(C2) = 5/6$
 $Gini = 1 - (1/6)^2 - (5/6)^2 = 0.278$

$$P(C1) = 2/6$$
 $P(C2) = 4/6$
 $Gini = 1 - (2/6)^2 - (4/6)^2 = 0.444$

Splitting Based on GINI

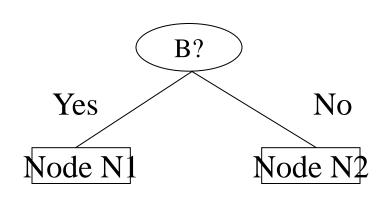

- Used in CART, SLIQ, SPRINT.
- When a node p is split into k partitions (children), the quality of split is computed as,

$$GINI_{split} = \sum_{i=1}^{k} \frac{n_i}{n} GINI(i)$$

where, n_i = number of records at child i, n = number of records at node p.

Binary Attributes: Computing GINI Index

- Splits into two partitions
- Effect of Weighing partitions:
 - Larger and Purer Partitions are sought for.

	Parent
C1	6
C2	6
Gini	= 0.500

Gini(N1)
$= 1 - (5/6)^2 -$
$(2/6)^2$
= 0.194

Gi	ni(N2)	
=	1 -	- (1	$(6)^{2}$	_
(4	/6)2		

	N1	N2				
C1	5	1				
C2	2	4				
Gini=0.333						

Gini(Children) = 7/12 * 0.194 + 5/12 * 0.528 = 0.333

Categorical Attributes: Computing Gini Index

- For each distinct value, gather counts for each class in the dataset
- Use the count matrix to make decisions

Multi-way split

	CarType									
	Family	Family Sports Luxury								
C1	1	2	1							
C2	4 1 1									
Gini	0.393									

Two-way split (find best partition of values)

	CarType							
	{Sports, Luxury} {Family							
C1	3	1						
C2	2 4							
Gini	0.400							

	CarType						
	{Sports}	{Family, Luxury}					
C 1	2	2					
C2	1 5						
Gini	0.419						

Continuous Attributes: Computing Gini Index

- Use Binary Decisions based on one value
- Several Choices for the splitting value
 - Number of possible splitting values
 Number of distinct values
- Each splitting value has a count matrix associated with it
 - Class counts in each of the partitions, A
 v and A > v
- Simple method to choose best v
 - For each v, scan the database to gather count matrix and compute its Gini index
 - Computationally Inefficient! Repetition of work.

Tid	Refund	Marital Status	Taxable Income	Cheat
1	Yes	Single	125K	No
2	No	Married	100K	No
3	No	Single	70K	No
4	Yes	Married	120K	No
5	No	Divorced	95K	Yes
6	No	Married	60K	No
7	Yes	Divorced	220K	No
8	No	Single	85K	Yes
9	No	Married	75K	No
10	No	Single	90K	Yes

Continuous Attributes: Computing Gini Index...

- For efficient computation: for each attribute,
 - Sort the attribute on values
 - Linearly scan these values, each time updating the count matrix and computing gini index
 - Choose the split position that has the least gini index

	Cheat		No		No		N	0	Ye	s	Ye	s	Υe	es	N	0	N	0	N	No No

Alternative Splitting Criteria based dn INFO

Entropy at a given node t:

$$Entropy(t) = -\sum_{j} p(j|t) \log p(j|t)$$

(NOTE: $p(j \mid t)$ is the relative frequency of class j at node t).

- Measures homogeneity of a node.
 - Maximum (log n_c) when records are equally distributed among all classes implying least information
 - Minimum (0.0) when all records belong to one class, implying most information
- Entropy based computations are similar to the GINI index computations

Examples for computing

Entrony

$$Entropy(t) = -\sum_{j} p(j|t) \log_{2} p(j|t)$$

C1	0
C2	6

$$P(C1) = 0/6 = 0$$
 $P(C2) = 6/6 = 1$
Entropy = $-0 \log 0 - 1 \log 1 = -0 - 0 = 0$

C1	1
C2	5

$$P(C1) = 1/6$$
 $P(C2) = 5/6$
Entropy = $-(1/6) \log_2 (1/6) - (5/6) \log_2 (1/6)$
= 0.65

$$P(C1) = 2/6$$
 $P(C2) = 4/6$
Entropy = - (2/6) $log_2(2/6) - (4/6) log_2(4/6)$
= 0.92

Splitting Based on INFO...

Information Gain:

$$GAIN_{split} = Entropy(p) - \left(\sum_{i=1}^{k} \frac{n_i}{n} Entropy(i)\right)$$

Parent Node, p is split into k partitions;

- n_i is number of records in partition i
- Measures Reduction in Entropy achieved because of the split.
 Choose the split that achieves most reduction (maximizes GAIN)
- Used in ID3 and C4.5
- Disadvantage: Tends to prefer splits that result in large number of partitions, each being small but pure.

Splitting Based on INFO...

Gain Ratio:

$$GainRATIO_{split} = \frac{GAIN_{Split}}{SplitINFO}$$

$$= \frac{GAIN_{Split}}{SplitINFO} \left| SplitINFO = -\sum_{i=1}^{k} \frac{n_i}{n} \log \frac{n_i}{n} \right|$$

Parent Node, p is split into k partitions n_i is the number of records in partition i

- Adjusts Information Gain by the entropy of the partitioning (SplitINFO). Higher entropy partitioning (large number of small partitions) is penalized!
- Used in C4.5
- Designed to overcome the disadvantage of Information Gain

Splitting Criteria based on Classification Error

Classification error at a node t :

$$Error(t) = 1 - \max_{i} P(i \mid t)$$

- Measures misclassification error made by a node.
 - Maximum (1 1/n_c) when records are equally distributed among all classes, implying least interesting information
 - Minimum (0.0) when all records belong to one class, implying most interesting information

Examples for Computing Error $Error(t) = 1 - \max P(i \mid t)$

C1 P(C1) = 0/6 = 0 P(C2) = 6/6 = 10 C2 6

C1	1
C2	5

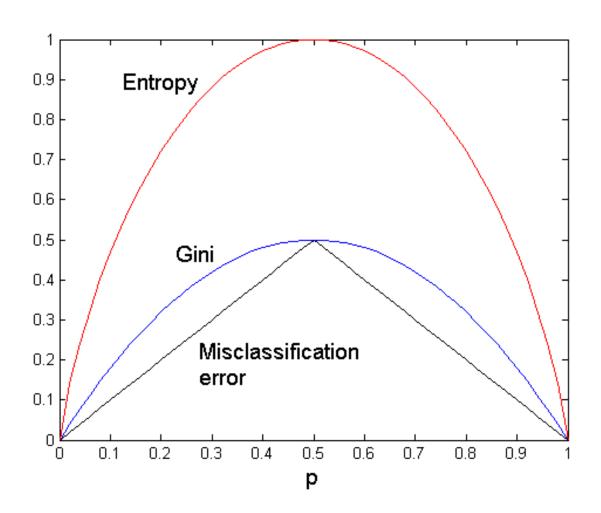

$$P(C1) = 1/6$$
 $P(C2) = 5/6$
 $Error = 1 - max (1/6, 5/6) = 1 - 5/6$
 $= 1/6$

Error = $1 - \max(0, 1) = 1 - 1 = 0$

$$P(C1) = 2/6$$
 $P(C2) = 4/6$
 $Error = 1 - max(2/6, 4/6) = 1 - 4/6 = 1/3$

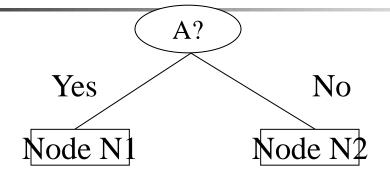

Comparison among Splitting

Criteria For a 2-class problem:

Misclassification Error vs Gini

	Parent	
C1	7	
C2	3	
Gini = 0.42		

Gini(N1)
=
$$1 - (3/3)^2 - (0/3)^2$$

= 0

Gini(N	12)
= 1 -	$(4/7)^2$
$(3/7)^2$	2
= 0.48	39

	N1	N2
C1	3	4
C2	0	3

Tree Induction

- Greedy strategy.
 - Split the records based on an attribute test that optimizes certain criterion.

Issues

- Determine how to split the records
 - How to specify the attribute test condition?
 - How to determine the best split?
- Determine when to stop splitting

Stopping Criteria for Tree Induction

 Stop expanding a node when all the records belong to the same class

 Stop expanding a node when all the records have similar attribute values

Early termination (to be discussed later)

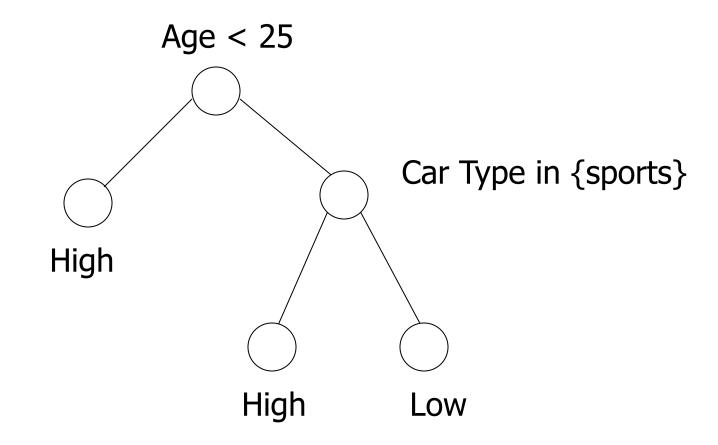

Why Decision Tree Model?

- Relatively fast compared to other classification models
- Obtain similar and sometimes better accuracy compared to other models
- Simple and easy to understand
- Can be converted into simple and easy to understand classification rules

A Decision Tree

Decision Tree Classification

- A decision tree is created in two phases:
 - Tree Building Phase
 - Repeatedly partition the training data until all the examples in each partition belong to one class or the partition is sufficiently small
 - Tree Pruning Phase
 - Remove dependency on statistical noise or variation that may be particular only to the training set

Tree Building Phase

General tree-growth algorithm (binary tree)

Partition(Data S)

```
If (all points in S are of the same class) then return;
```

for each attribute A do

evaluate splits on attribute A;

Use best split to partition S into S1 and S2;

Partition(S1);

Partition(S2);

Tree Building Phase (cont.)

- The form of the split depends on the type of the attribute
- Splits for numeric attributes are of the form A ≤ v, where v is a real number
- Splits for categorical attributes are of the form A ∈ S', where S' is a subset of all possible values of A

Splitting Index

- Alternative splits for an attribute are compared using a splitting index
- Examples of splitting index:
 - Entropy (entropy(T) = $\Sigma p_j \times \log_2(p_j)$)
 - Gini Index (gini(T) = $1 \Sigma p_j^2$) (p_j is the relative frequency of class j in T)

4

The Best Split

- Suppose the splitting index is I(), and a split partitions S into S1 and S2
- The best split is the split that maximizes the following value:

 $I(S) - |S1|/|S| \times I(S1) + |S2|/|S| \times I(S2)$

Tree Pruning Phase

- Examine the initial tree built
- Choose the subtree with the least estimated error rate
- Two approaches for error estimation:
 - Use the original training dataset (e.g. cross –validation)
 - Use an independent dataset
